Figure 1: Client behind a Cone NAT/PAT. All requests with a given port (8000) are masqueraded. The next, and subsequent requests made to different destination addresses with that port are masqueraded to the same port. In addition, unsolicited responses from others addresses are forwarded, regardless of source port.

Figure 2- Client behind a Port-Restricted Cone NAT/PAT. All requests with a given port (8000) are masqueraded. The next, and subsequent requests made to different destination addresses with that port are masqueraded to the same port. In addition, unsolicited responses from others addresses are forwarded, so long as the source port matches the destination port of the original request.

First request and response

Second request and response.

Third party, unsolicited response with mismatched source port is not forwarded.

Third party, unsolicited response with matched source port is forwarded.

Figure 3: Client behind a Symmetric NAT/PAT. All requests with a given port (8000) are masqueraded. The next, and subsequent requests made to different destination addresses with that port are masqueraded to different ports. In addition, unsolicited responses from others addresses are not forwarded, because the source addresses do not match the destination of the original request. Most symmetric firewalls also require the source port to match the destination port of the original request (full tuple match).
